## PREFACE

The appendixes in this volume are intended to provide the user with the technical information needed to reproduce the simulation program used in the analysis and to process additional samples of AUTODIN traffic. While the appendixes are complete, the user may benefit from reviewing the logical cost model as it is developed in Chapter II of Volume I.

APPENDIX C

SIMULATION PROGRAM DOCUMENTATION

## SIMULATION PROGRAM DOCUMENTATION

The IDADIN computer model, the IDA version of the DCA automated AUTODIN Costing Model, consists of two Fortran programs on cards and various data files residing on both cards and tape. Described in this appendix are (1) the coding scheme and processing sequence for model operation, (2) the structure and programming logic of the Fortran routines, and (3) the formats of the various data files and user-defined input parameters. Sample output and listings of the Fortran programs DNCOSTCD and IDADIN are included.

### A. CODING SCHEME FOR MODEL OPERATION

The DCA AUTODIN I system is a computer-controlled "store and forward" digital communications network that receives, stores, and transmits data to predetermined addresses on a worldwide basis. The 17 interconnected store-and-forward stations (computers) in the network are referred to as AUTODIN Switching Centers (ASCs) or, for convenience, "switches." Authorized users access the system from terminals or computers by means of circuits or channels continuously connecting them to a particular ASC. Each connection, a unique channel-switch combination is referred to as a system tributary and, depending on the speed of the transmitting equipment used, is classified as slow (transmits at 75, 150, or 300 baud), medium (600-1200 baud) or high (2400-4800 baud). Because of these varying transmission speeds, the Central Processing Unit (CPU) of each switch is augmented by the additional memory capacity of the Accumulation and Distribution Unit (ADU) which (1) stores

incoming messages until the CPU can handle them, and (2) matches the output rate to that of the receiving equipment. The following codes, based on the features of the AUTODIN network just described, are associated with each AUTODIN message transmission for cost accounting purposes.

- (1) Program Designator Code (PDC). A four-character alphanumeric code consisting of the subscriber agency code (initial character) and the program-within-agency code (remaining three characters). Currently, there are 1300 subscribers accounting for 150 programs of 13 user agencies.
- (2) Tributary Code. A combined code consisting of a three-character alphanumeric originating switch name and a three-character alphanumeric originating channel name (currently 1300 access lines among 17 switches).
- (3) Routing Indicator (RI) Code. A six-character alphanumeric code that identifies either the origin or destination circuit/terminal for the message transmission. This code is available but not used in IDADIN processing.
- (4) Values for weighting ADU memory costs by speed class of access line. Weights of 3, 9, and 14 are used for low, medium, and high connections, respectively.

#### B. PROCESSING SEQUENCE FOR MODEL OPERATION

A schematic of the overall processing sequence for the IDADIN model is shown in Figure C-1. Data for AUTODIN traffic are collected over all the ASCs in "traffic files," each file (a "raday") representing one day's traffic. The traffic files and the AMIE Extract File are first sequenced by utility sort for input to the preliminary program DNCOSTCD. During this procedure the records of the Traffic File simultaneously are reduced in length to seven elements of information, sequenced in ascending order of originating switch name, originating channel name, and RI code, and, if more than one file, merged into a single file. Then, by matching the sequenced Traffic File to both the sequenced AMIE Extract File and the Switch Name File, DNCOSTCD produces as output the STASUB File, a revised traffic file

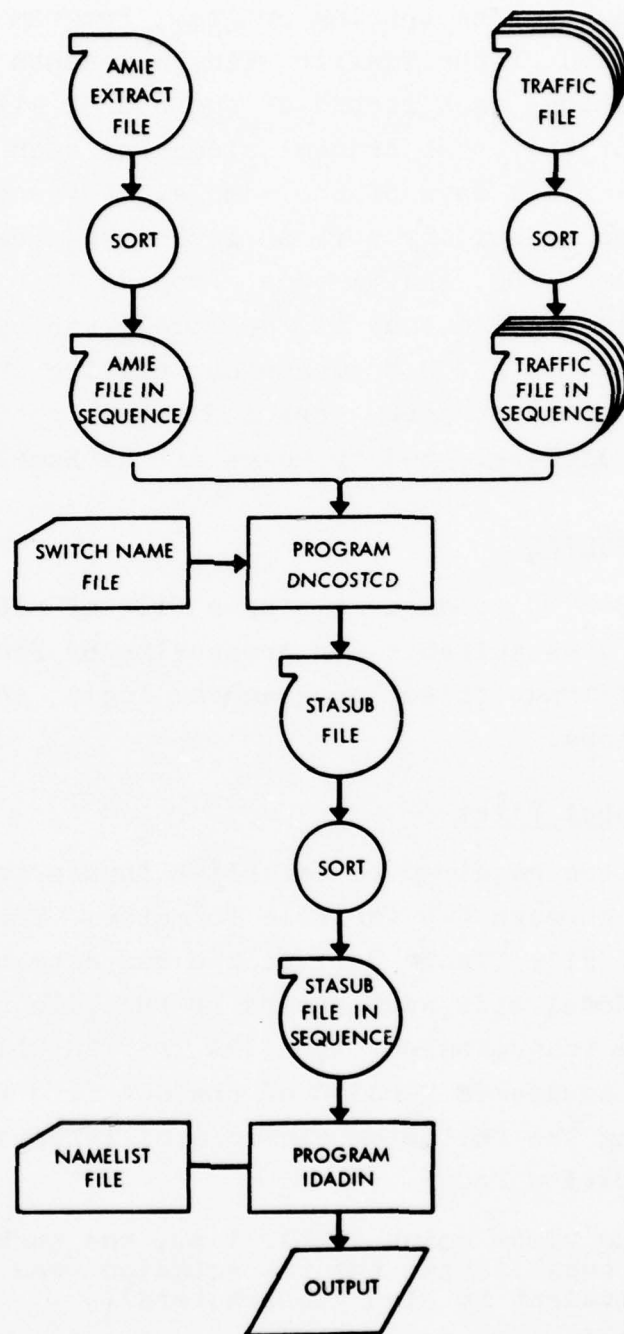

Figure C-1. SCHEMATIC OF PROCESSING SEQUENCE FOR THE IDADIN COSTING MODEL

suitable for input to the costing program, Program IDADIN. Whereas each record of the Traffic File represents a single message transmission, each record of the STASUB File represents an aggregation of the total transmissions for each tributary on the system over all days of the sample. After the STASUB File is sequenced by utility sort in ascending order of switch name, channel name, PDC, and RI code, Program IDADIN processes it to produce, as final output of the model, various costing analyses pertinent to AUTODIN subscriber billing charges. As will be described, input parameters and output options for Program IDADIN are user-selected by means of the Namelist File.

### C. PROGRAM DNCOSTCD

Program DNCOSTCD produces a single file of subscriber-coded AUTODIN traffic data suitable for processing by Program IDADIN. A description of input files, programming logic, and DNCOSTCD subprograms follows.

#### 1. DNCOSTCD Input Files

Four files are required to establish inputs to DNCOSTCD (see Tables C-1 through C-4 for file formats). The DCA Sorted Assemble Traffic File (Table C-1) is the raw data base for the IDADIN Costing Model with each record of the file representing a single message transmission. The IDA Traffic File (Table C-2) is a sequenced, condensed version of the DCA file with each record containing the following elements of information relevant to the IDADIN Costing Model:

- (1) The line block count (LBC), i.e., the number of line blocks constituting the transmission (one line block is equivalent to eighty characters).
- (2) The originating switch and channel names (the origin tributary).
- (3) The destination switch and channel names (destination tributary).
- (4) The message precedence (priority).

Table C-1. FILE FORMAT FOR DCA SORTED ASSEMBLE TRAFFIC FILE

Field	Record Position	Fortran Variable Name	Format	Item
1	1-3	W(1)	A3	Raday (not used)
2	4	W(2)	A1	Precedence (Z = FLASH)

Table C-2. FILE FORMAT FOR IDA TRAFFIC FILE

Field	Record Position	Fortran Variable Name	Format	Item
1	1-3	W(1)	A3	Destination Channel Name
2	4	W(2)	A1	Precedence (Z = FLASH)
3	5-7	W(3)	A3	Origin Switch Name
4	8-10	W(4)	A3	Origin Channel Name
5	11-13	W(5)	A3	Destination Switch Name
6	14-16	W(6)	I3	Line Block Count
7	17-22	W(7)	A6	Origin RI

File Name: IDA Traffic File

Fortran Reference: TAPE 1 (Tape Input)

Source: Institute for Defense Analyses

The AMIE Extract File, Table C-3, a condensed version of the DCA Auditing Management Index File (AMIE), contains a list of PDCs and bauds (transmission speeds) associated with each tributary appearing on the Traffic File. These two files are matched on tributaries, i.e., on switch name/channel name combinations. Similarly, the Switch Name File, Table C-4, contains a geographic location code (C = CONUS, E = Europe, P = Pacific) for each of the 17 switches on the AUTODIN system. This file is matched to the Traffic File by switch name.

Table C-3. FILE FORMAT FOR AMIE EXTRACT FILE

Field	Record Position	Fortran Variable Name	Format	Item
1	1-3	AMIE(1)	A3	Origin Switch Name
2	4-6	AMIE(2)	A3	Origin Channel Name
3	7-10	AMIE(3)	A4	PDC
4	11-14	AMIE(4)	A4	Baud Rate

File Name: AMIE Extract File

Table C-4. FILE FORMAT FOR SWITCH NAME FILE

Field	Card Column	Fortran Variable Name	Format	Item
1	1-3	J	A3	Switch Name
2	4	K	A1	Geographical Area

File Name: Switch Name File

Fortran Reference: TAPE 5 (Card Input)

## 2. DNCOSTCD Programming Logic

By sequential matching of the ordered records of the input files described above, Program DNCOSTCD both revises and aggregates the records of the IDA Traffic File in the following four ways. (1) The baud and PDC from an AMIE Extract File record and the origin switch name, origin channel name, and RI from a matching Traffic File record form the first five fields of the revised record. (2) The originating switch name and geographic location of the transmission are compared to the destination switch name and geographic location. If the originating and destination switch names match, the LBC for the record is designated local traffic and if the message has priority (a "FLASH" message) the LBC is also designated as local FLASH data. Similarly, if only the geographic areas match, the LBC is designated as area traffic or FLASH area traffic. If neither switch nor geographic areas match, the LBC is designated inter-area or FLASH inter-area. Thus, the LBC for a given transmission is assigned one of the next six fields on the new record according to its geographic designation and precedence category. (It should be noted that the count of FLASH LBCs on any record is to be considered a subset of the total LBC count.) (3) A new traffic record is read. If the origin switch name/channel name combination contained on the record does not match that on the AMIE Extract record just processed, a new AMIE record is read (thus effecting the next match) and a new tributary record is constructed as described. If the next tributary does match the preceding AMIE record, however, the LBC counts are added into the counts just established for the preceding match. (4) Finally, the remaining six fields of the tributary record are used to record the number of message transmissions occurring for the tributary. The counts are incremented with each match of a traffic record to a preceding AMIE record, and their placement on the record corresponds to the geographic designation-precedence categories used for the LBC counts with the exception

that an additional field is used to tally total number of messages for the tributary.

A more specific description of this processing sequence is shown in the flow chart in Figure C-2. Additional information is provided by means of comment cards on the DNCOSTCD Program Listing.

### 3. DNCOSTCD Subprograms

Two short subroutines are used in DNCOSTCD processing. Subroutine SORT is called to sort the input switch name location codes into collating sequence. The Integer Function Subprogram LOC is called in order to match both switch names on a given record with the sorted switch name file, thus allocating LBCs to the proper record field. In addition to SORT and LOC, DNCOSTCD also uses two input file detection devices resident in the IDA CDC computer system program library. INCK allows a return to execution if illegal characters are encountered during a Fortran BCD input read rather than terminating the program with an error message. The EOF device is used to detect the end-of-file mark on the various input files and to branch program control to the appropriate point in the processing sequence.

### 4. DNCOSTCD Sample Output

Two types of printed output are produced in DNCOSTCD processing. Table C-5 shows a listing of the 17 switch name codes in the Switch Name File and their corresponding geographic identifiers. Table C-6 shows a formatted listing of the contents of the STASUB File produced as the primary output of the program.

## C. PROGRAM IDADIN

The purpose of the IDADIN computer model is to provide a method of allocating costs to the particular users having access to the AUTODIN system. Using a sample of message traffic, Program IDADIN performs a rate analysis and calculates backbone charges by user agency. In addition, various tables of possible cost allocations are generated. A description of the IDADIN input files, programming logic, cost model algorithm, and sub-programs follows. Sample output is included.

### 1. IDADIN Input Files

Two files are required inputs to Program IDADIN. The STA-SUB File (see Table C-7 for file format) contains for each tributary on the system its user identification codes (PDC and origin switch and channel names), transmission speed (baud), and volume of traffic (line block and message counts) over all days of the traffic sample. The second file is input on cards and stored as array LIST by means of the Fortran Namelist statement. This technique is employed in Program IDADIN to enable the user to vary cost allocation model input parameters and to select output options for each iteration of the cost algorithm. The array LIST is established by the user in the following manner. A value is selected for each variable specified by the Namelist statement (see Table C-8). The variable names and values are then punched on input cards in "free format," i.e., they are punched in the order specified by the Namelist statement but without regard to the field position. (Similarly, when the list is input or output, no format specifications are required.) Each input list must begin with a \$ in Column 2 of the first card, followed immediately by the word LIST with no embedded blanks. A \$ must also follow the last variable in the list. The data items, separated by commas, may be in any of three forms:

Table C-7. FILE FORMAT FOR STASUB FILE

Field	Record Position	Fortran Variable Name	Format	Item
1	1-3	W(1)	A3	Originating Switch Name
2	4-6	W(2)	A3	Originating Channel Name
3	7-12	W(3)	A6	Routing Indicator Code
4	13-16	W(4)	A4	Program Designator Code
5	17-20	W(5)	I4	Transmission, Speed, baud
6	21-29	W(6)	I9	Number of Local Line Blocks
7	30-38	W(7)	I9	Number of Area Line Blocks
8	39-47	W(8)	I9	Number of Inter-area Line Blocks
9	48-53	W(9)	I6	Number of Local FLASH Line Blocks
10	54-59	W(10)	I6	Number of Area FLASH Line Blocks
11	60-65	W(11)	I6	Number of Inter-area FLASH Line Blocks
12	66-72	--	--	Blank
13	73-80	W(12)	I8	Total Number of Messages
14	81-89	W(13)	I9	Number of Local Messages
15	90-98	W(14)	I9	Number of Area Messages
16	99-107	W(15)	I9	Number of Inter-area Messages
17	108-116	W(16)	I9	Number of Local FLASH Messages
18	117-125	W(17)	I9	Number of Area FLASH Messages
19	126-134	W(18)	I9	Number of Inter-area FLASH Messages

File Name: STASUB File

Fortran Reference: TAPE 1 (Tape Input)

Table C-8. NAMELIST FILE INPUT VARIABLES

Variable Name	Output Item	Value Producing Sample Output <sup>1</sup>	Definition
SWCOST	Switch Cost, \$	845080	This value x 52 is the approximate lease and O&M costs for all switching centers in FY 78.
MCOST	ADU Memory Cost, \$	169016	This value x 52 is the estimate of ADU lease costs. Nine leased switches assuming two ADUs per switch.
TRKC	Number of Area Trunk Terminations	56	Count of leased switch interconnections.
TRKI	Number of Inter-area Terminations	17	Number of trunk terminations at leased switches from overseas.
TRIC	CONUS Trunk Costs, \$	6846	Defined as cost of all area trunks, i.e., trunks connecting switches in same charging area (CONUS, Europe, etc.). Value here x 52 is for CONUS trunks only.
TROC	Overseas Trunk Costs, \$	34269	Defined as cost of trunks connecting switches in different areas. Value used here is for CONUS trunks only.
LBLKS	Area Memory Capacity, Line Blocks	21060	Line blocks of ADU memory is all leased switches assuming eighteen ADUs and eight quadrants of memory per ADU (Hawaii switch is included with CONUS).
BRKDWN	n.a.	.TRUE.	Output Control Variable. If BRKDWN = .TRUE., output produced for AUTODIN Costs by Program Designation Code for utilization, connectivity, and total costs. If BRKDWN = .FALSE., output suppressed.
SPDBLK	Not shown in output	3, 9, 14	Weights (slow, medium, high) used to calculate monthly basic charge for connectivity.
FLASH	Usage Cost Factor: FLASH Weights	0.0	Single weight applied to all FLASH messages (may take on any value).
BLOCKS	Usage Cost Factor (if line blocks, 1.0; if messages, 0.0)		A 0.0 value for BLOCKS is equivalent to assigning all usage charges on a message basis. A 1.0 value assigns all message charges on a line block basis. Calculated after all surcharges have been deducted. Values may range between 0 and 1.
MSGCHG	Surcharges: local, area, inter-area	.10, .15, .30 (0.0 for FLASH)	These surcharges are applied on a per-message basis and subtracted from costs to be collected through usage before calculation of line block and message rates. May take on any value.
MSGWTS	Not shown	1, 1, 1	A set of weighting factors for local, area, and inter-area non-FLASH messages. May take on any value.
PRTTA	n.a.	.TRUE.	Output Control Variable. If PRTTA = .TRUE., output produced for subroutines CNCT and ATA. If PRTTA = .FALSE., output suppressed.

<sup>1</sup>See IDA AUTODIN Cost Allocation Model Output.

$v = c$

$a = d_1, \dots, d_j$

$a(n) = d_1, \dots, d_m$

where  $v$  is a variable name,  $c$  a constant,  $a$  an array name, and  $n$  an integer subscript. The  $d_i$  are simple constants or repeated constants of the form  $k*c$ , where  $k$  is the repetition factor.

For example, \$ SWCOST = 845080, MCOST = 169016, TRKC = 56, ..., PRTTA = .TRUE.\$. A special feature of the use of the Namelist in IDADIN is that those variables shown in Table C-8 as already containing values are used as default inputs. To use them by default, the user merely omits them from his input list. An additional feature is that the output from Subroutines CNNCT and ATA can be suppressed by resetting the logical variable PRETTA to .FALSE.. Similarly, the output for AUTODIN I costs by program designator code can be suppressed by setting the logical variable BRKDOWN to .FALSE..

## 2. IDADIN Processing Sequence

Program IDADIN processing proceeds as follows: (1) the Namelist File is read in, thus setting up array LIST with an ordered list of model parameters. (2) Subroutine Sample is called to place into the labeled common block PCA an alpha-numeric representation of the number of days (IOPT) in the traffic sample. This provides a convenient way to display the sample size in all the output headers. (3) Next, if the user has not suppressed them by means of the input control variable PRTTA, two subroutines are called: Subroutine CNNCT calculates and outputs a breakdown of total ADU memory utilization by switch and connectivity speed class (see Table C-9). Subroutine ATA is called to calculate an AUTODIN I Traffic Analysis (7-day sample). The output of this analysis (see Appendix B) is organized in the following manner. The first table, "System Access Analysis," presents by agency the number of connections

Table C-9. PROGRAM IDADIN OUTPUT: ADU MEMORY  
UTILIZATION, LINE BLOCKS, BY SWITCH  
AND CONNECTIVITY SPEED CLASS

Switch	Slow	Medium	High	Percent

by speed class and the percent each value is of the agency, the system, and the total. The next nine tables are a breakdown by agency for local, area, inter-area, and total traffic (both regular and FLASH) for the following items:

- (a) total line blocks
- (b) line blocks as percent of agency traffic
- (c) line blocks as percent of system traffic
- (d) line blocks as percent of total system traffic
- (e) total messages
- (f) messages as percent of agency traffic
- (g) messages as percent of system traffic
- (h) messages as percent of total system traffic
- (i) line blocks per message.

The remaining table (see sample in Table C-10) is a summary of all the preceding tables by PDC code rather than by agency.

(4) Using the parameters specified in the Namelist File, all cost factors are calculated. Then, Subroutine TAB is called to print the report of the resulting cost allocation by Program Designator Code (see Table C-11). (5) Subroutine OUTPUT is

called to organize the first portion of a convenient summary of the cost allocation model in terms of the input parameters specified by the user, sample characteristics, and the rate analysis. (6) Control is returned to the main program to calculate and print out, as the final portion of the summary, the backbone charges by agency. (7) The final section of the program rewinds the STASUB File and processes and prints out the second user output option if specified, i.e., a full analysis by switch for each PDC (see Table C-12 for sample). At this point, a new namelist card(s), if any, is read in and processing starts again for another full run of the program. A more detailed description of the cost allocation model algorithm is described in the following section.

### 3. Cost Model Allocation Algorithm

The IDA AUTODIN Cost Allocation Model (see Table C-13 for sample results) disaggregates the network according to hardware and message traffic characteristics in order to produce an algorithm for charging agencies for use of the system. Factors such as the number of switches and trunks, the area switch memory capacity, the type (speed) of connectivity into the backbone, the speed and destination of messages, and the total message volume all affect the allocation of AUTODIN backbone cost. A formula using these factors breaks down the total system charges and assigns them to agencies. The formula is

$$T_1 = \sum_{j=1}^3 w_j N_j + A_1(x_1 + y_1 + z_1) + A_2(y_1 + z_1) + A_3(z_1) + A_4 F_1$$

where

$T_1$  = total PDC charges according to transmission unit

$j$  = baud category

$N_j$  = number of access lines of speed  $j$

$w_j$  = weighted connectivity charge of speed  $j$

A = utilization rate charged for message traffic  
i = transmission unit, either line blocks or messages  
 $x_i$  = volume of 'LOCAL' transmission units  
 $y_i$  = volume of 'AREA' transmission units  
 $z_i$  = volume of 'INTER-AREA' transmission units  
 $F_i$  = volume of 'FLASH' transmission units.

In order to use this allocation formula several steps are followed. First, input parameters for the network are identified. These include total costs of the system, apportioned into percentages for switches and trunks, switch memory ratios (area and inter-area trunk terminations divided by line blocks passing through the switch), and arbitrary weights and surcharges for segmenting message traffic in a utilization pricing structure. Next, message traffic of the particular sample is examined in terms of geographical destination (local, area, or inter-area), and total traffic is broken down into separate line blocks and message counts. FLASH traffic, given top priority in transmission, is treated as a subcategory with the same breakdown so that both weights and surcharges can be assessed. In addition, the number of access lines is accumulated consistently with three groupings for transmission speeds (75-300 baud, 600-1200 baud, and 2400-4800 baud).

Third, PDC charges are set to be allocated using the connectivity/utilization ratio deemed optimal. Rates for connectivity typically have a standard connection charge for access to the network and a progressive rate scaled for the three transmission speed categories. Depending on the transmission unit used for message traffic--line blocks or messages--utilization rates are prorated according to precedence (FLASH or regular traffic) and geographical destination. Finally, total backbone charges are accumulated for each agency with subtotals for utilization and connectivity.

#### 4. The IDADIN Subprograms

The 16 IDADIN subprograms fall into three general categories: procedural, functional, and output.

a. The Procedural Subprograms. Subroutine CNNCT produces a breakdown of total ADU memory utilization by switch (Table C-9). Subroutine ATA performs the agency traffic analysis, aggregating by the first letter of the program designator code, and produces the formatted printed output report shown in Appendix B. Subroutine PRTATA is called by ATA to print the final summary table for the traffic analysis (Table C-10). Subroutine CHARGE computes the cost allocation to any charging point (tributary) using the cost allocation model outlined earlier. Arguments to the procedure supply information on the volume of traffic generated by the charging point and the parameters of the cost allocation model itself. Subroutine OUTPUT produces the formatted printed output report of the results of the cost allocation model (Table C-13) and Subroutine TAB prints out the results by program designator code.

b. The Functional Subprograms. Subroutine PCT is called by Subroutine ATA to compute percentages of the agency total, system total in that class, and the overall system total (Table C-10). Integer Function MATCH performs an integer linear search when called. Integer Function SPDCLS returns as its function value the integer one, two, or three corresponding to the class of speed to which the argument belongs. Real Function TOTAL returns as its function value the sum of the values of its real argument array and Integer Function SUM returns as its function value the sum of its integer argument array. Subroutine CLEAR is used to zero an area of memory.

c. The Output Routines. Subroutine SAMPLE computes and places into common block PCA an alphanumeric representation of the numbers of days in the traffic sample. Subroutine TITLE

prints the heading line on each page of printed output, sequentially numbering all pages starting with Page 1. It also prints the number of days in the sample using results supplied by Subroutine SAMPLE. Subroutine CENTER produces a line of printed output in which the argument to the subroutine is printed in the middle of the output page. Subroutine PAGE is used to control pagination and spacing in the output reports.
